

Self -healing of teeth from the decay.

According to new scientific data the dental filings probably soon should belong to the past. Experts from the University of California support that the dentine of teeth is likely to be anaplastic and to be developed again with the help of a solution of electrically charged particles that contain calcium.

The re-calcification of the adamantine, that is to say of the outer part of tooth is an acceptable scientifically phenomenon but for the dentine there are not yet enough given the complexity of its structure.

These specialists believe that the coming years they will be able to identify teeth with caries at an early stage and will be able to restore them re-calcifying them significantly.
